This revision incorporates comments from the public.

The National Cybersecurity Center of Excellence (NCCoE), a part of the National Institute of Standards and Technology (NIST), is a collaborative hub where industry organizations, government agencies, and academic institutions work together to address businesses' most pressing cybersecurity challenges. Through this collaboration, the NCCoE develops modular, easily adaptable example cybersecurity solutions demonstrating how to apply standards and best practices by using commercially available technology. To learn more about the NCCoE, visit <https://nccoe.nist.gov>. To learn more about NIST, visit <http://www.nist.gov>.

This document describes a challenge that is relevant across the Energy Sector. NCCoE cybersecurity experts will address this challenge through collaboration with members within the energy industry and with cybersecurity technology providers. The resulting example solution will detail an approach that can be used by the Energy Sector.

### **ABSTRACT**

Industrial control systems (ICS) comprise a core part of our nation's critical infrastructure. Energy sector companies rely on ICS to generate, transmit, and distribute power and to drill, produce, refine, and transport oil and natural gas. There are a wide variety of ICS assets, such as supervisory control and data acquisition (SCADA) systems, distributed control systems (DCS), programmable logic controllers (PLCs), and intelligent electronic devices (IEDs), that provide command and control information and functions on operational technology (OT) networks. These assets are primary targets of cyber attacks. Vulnerabilities within these systems and devices present opportunities for malicious actors to cause disruptions to the power grid and to oil and gas assets and processes.

Energy Sector companies must monitor and manage ICS assets at all times to reduce the risk of such attacks. The NCCoE, in collaboration with members of the energy community and with cybersecurity technology providers, is planning a project to create an example solution to address this complex asset management challenge. This project will result in a freely available NIST Cybersecurity Practice Guide that includes an example solution for electric utilities and for oil and gas companies to effectively track and manage their assets.

### **KEYWORDS**

Energy Sector Asset Management (ESAM); industrial control systems (ICS); malicious actor; monitoring; operational technology (OT); supervisory control and data acquisition (SCADA)

### **DISCLAIMER**

Certain commercial entities, equipment, products, or materials may be identified in this document to adequately describe an experimental procedure or concept. Such identification is not intended to imply recommendation or endorsement by the National Institute of Standards and Technology or the National Cybersecurity Center of Excellence, and it is not intended to imply that the entities, equipment, products, or materials are necessarily the best available for the purpose.

# 1 EXECUTIVE SUMMARY

## Purpose

The National Cybersecurity Center of Excellence (NCCoE) is responding to the Energy Sector's request for an operational technology (OT) asset management solution. To remain fully operational, Energy Sector entities should be able to effectively identify, control, and monitor all of their OT assets. This project will provide guidance on how to enhance OT asset management practices by leveraging capabilities that may already exist in an operating environment or by implementing new capabilities.

The publication of this project description initiates the process to identify project collaborators, as well as standards-based, commercially available, and/or open-source technologies. These products will be implemented in a laboratory environment to build a standards-based, modular, end-to-end example solution that will address the security challenges of OT asset management. The approach will include architectural definition, physical and logical design, a comprehensive security analysis, security control mapping, and future build considerations. The output of the process will be the publication of a multi-volume National Institute of Standards and Technology (NIST) Cybersecurity Practice Guide that organizations can use to enhance their ability to improve Energy Sector asset management.

## Scope

This project will seek to address the following characteristics of asset management:

- **Asset Discovery:** establishment of a full baseline of physical and logical locations of assets
- **Asset Identification:** capture of asset attributes, such as manufacturer, model, operating system (OS), Internet Protocol (IP) addresses, Media Access Control (MAC) addresses, protocols, patch-level information, and firmware versions
- **Asset Visibility:** continuous identification of newly connected or disconnected devices, and IP (routable and non-routable) and serial connections to other devices
- **Asset Disposition:** the level of criticality (high, medium, or low) of a particular asset, its relation to other assets within the OT network, and its communication (to include serial) with other devices
- **Alerting Capabilities:** detection of a deviation from the expected operation of assets

## Assumptions

This project identifies security benefits, including the automated identification of OT assets to enable quick security alerts and increased cybersecurity resilience.

This project makes the following assumptions:

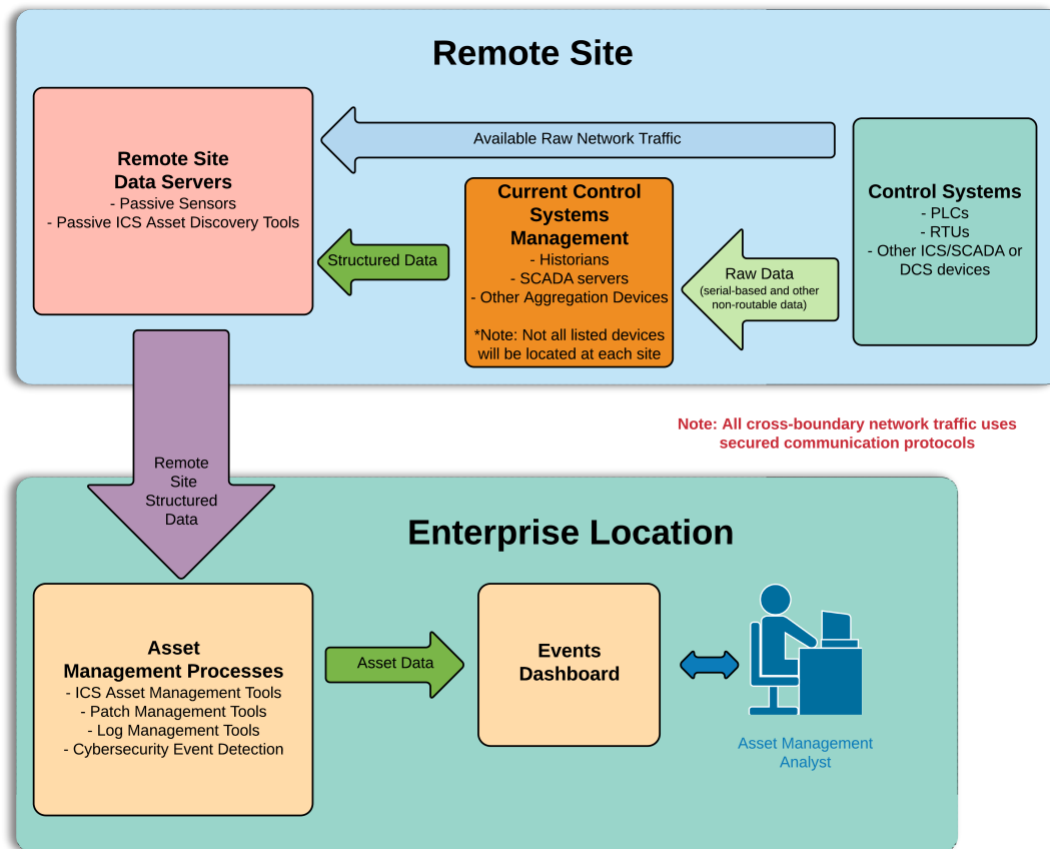

- Some level of an asset management capability already exists within an organization.
- All OT assets within an organization's infrastructure, especially those that are considered critical, need to be identified, tracked, and managed.
- OT networks are comprised of numerous ICS devices, such as programmable PLCs and IEDs, in addition to other vital components, such as engineering workstations, historians, and human-machine interfaces (HMIs), which are typically installed on a Windows and/or Linux OS.

## Background

The NCCoE, in collaboration with organizations in the Energy Sector, identified the need to strengthen their asset management capabilities, especially for assets that are geographically dispersed. Vulnerabilities in OT assets present opportunities for malicious actors to cause disruptions to both electrical grid and oil and natural gas infrastructure. Such disruptions can result in economic loss and the interruption of critical services to millions of people. To properly assess cybersecurity risk within the OT network, energy companies must be able to identify all of their assets, especially those that are most critical. This project will describe a reference architecture and an example solution for managing, monitoring, and baselining assets, and will also include information to help identify threats to these OT assets. An OT asset management solution may also serve as a key component of an organization's comprehensive asset inventory, including enterprise assets as well.

## 2 HIGH-LEVEL ARCHITECTURE

The figure below depicts the proposed high-level environment and architecture to help improve asset management within an energy organization.

### Component List

Collaborating partners (participating vendors) will need to provide components to develop an example solution, including, but not limited to, the following components:

- OT/ICS-specific asset discovery and management tools
- Reliable/secure/encrypted communication devices

- Cybersecurity event/attack detection capability
- Log management/security information and event management (alerting)

### Desired Capabilities

The security capabilities of the example solution are as follows:

- OT/ICS asset inventory (to include devices using serial connections)
- High-speed communication mechanisms for remote asset management
- Reliable/secure/encrypted communications
- Continuous asset monitoring
- Log analysis and correlation
- Cybersecurity event/attack detection
- Patch level information
